

Scientific Figure Generation Comparison

Scientific Figure Generation Quality Evaluation

You will see a **Reference Image** and two images generated by different models (**Image A** and **Image B**). Please compare them against the reference and judge which is better across four dimensions. If the difference is negligible, select **Tie**.

Note: For dimensions 1-2, compare against the reference; for dimension 3, evaluate the generated image independently; dimension 4 is your overall preference.

1 Structural Faithfulness

Compare with reference: Are all modules present? Are arrow connections correct? Is the data flow logical? Is the hierarchy consistent? (Ignore style/color)

2 Text Accuracy

Are labels spelled correctly? Are formulas complete? Are key terms present? Is text legible without garbled characters?

3 Visual Quality

Without looking at the reference, evaluate the generated image alone: Is the layout clean? Is the color scheme harmonious? Are lines clear? Does it have publication-quality aesthetics?

4 Overall Preference

If you were to use one in your paper, which would you choose?

Please complete this evaluation on a desktop computer. This is a formal academic evaluation. Please carefully compare before making your choice. Thank you!

The figure illustrates the framework of Dynamic Feature Alignment, a method designed for domain adaptation using a dynamic memory bank to store class prototypes for alignment and pseudo-labeling. The global layout is horizontally structured, progressing from left to right: starting with input data sources on the far left, moving through feature extraction and memory storage in the center, and ending with the processing of unlabeled target data on the right. The central component is the 'Normalized Feature Space,' depicted as a gray circular region containing scattered colored points representing different feature types. Above this space is the 'Dynamic Memory Bank,' shown as a dashed rectangular box containing a table with rows labeled m_1 to m_K (memory entries) and corresponding y_1 to y_K (labels), where each row has alternating blue and green backgrounds for memory entries and peach-colored backgrounds for labels.

On the left side, two groups of images are presented: 'Labeled Source' at the top (in blue text) showing colorful, realistic images such as airplanes and books, and 'Labeled Target' at the bottom (in green text) displaying grayscale sketches of birds and cats. Both sets feed into a yellow trapezoidal module labeled 'F', representing the feature extractor. This module outputs features that are directed into the Dynamic Memory Bank and also projected into the Normalized Feature Space. In the feature space, labeled source features are represented by blue dots, labeled target features by green dots, and labeled features (from both domains) are shown as yellow dots. These features are used to form class prototypes stored in the memory bank.

On the right side, 'Unlabeled Target' data (in red text) consists of various hand-drawn sketches including bicycles, a teddy bear, and a cake. These images are processed by a second identical feature extractor 'F' (yellow trapezoid), which shares the same weights as the one on the left, ensuring consistent feature
